Power-up, Reset, Clock, and Standby Sequence

- Note: 1. All output signals are defined during initial power-up with RESET_BAR held LOW without SYSCLK being active. To properly reset the rest of the sensor, during initial power-up, assert RESET_BAR (set to LOW state) for at least 750ns after all power supplies have stabilized and SYSCLK is active (being clocked). Driving RESET_BAR to LOW state does not put the part in a low power state
2. Before using two-wire serial interface, wait for 10 SYSCLK rising edges after RESET_BAR is de-asserted.
3. Once the sensor detects that STANDBY has been asserted, it completes the current frame readout before entering standby mode. The user must supply enough SYSCLKs to allow a complete frame readout.
4. In standby, all video data and synchronization output signals are driven to a low state.
5. In standby, the two-wire serial interface is not active.
